Experiment 4

IMPLEMENTATION OF A* SEARCH ALGORITHM

Aim:

To implement A* Search Algorithm.

Case Scenario:

A delivery robot in a warehouse needs to find the shortest path from the entrance to a specific package location. The warehouse is represented as a grid with some obstacles. Implement the A* search algorithm to help the robot navigate efficiently.

Procedure:

1. Define the Node class with attributes: position, parent, cost (g), heuristic (h), and total cost ($f = g + h$).
2. Implement the heuristic function using the Manhattan distance formula.
3. Initialize A Search* with:

- open_list (priority queue) containing the start node.
- closed_set to store visited nodes.

4. While open_list is not empty:

- Extract the node with the lowest f-value.
- If the goal is reached, trace back the path and return it.
- Add the current node to closed_set.
- Generate new valid moves (up, down, left, right) ensuring they are within bounds and not obstacles.
- Calculate new cost g, heuristic h, and total f.
- Add new nodes to open_list for further exploration.

5. Return the optimal path if found, else return None if no path exists.

Program:

```
import heapq  
  
# Define the grid and movements
```

```

class Node:
    def __init__(self, position, parent=None, g=0, h=0):
        self.position = position # (row, col)
        self.parent = parent # Parent node
        self.g = g # Cost from start node
        self.h = h # Heuristic cost to goal
    self.f = g + h # Total cost
    def __lt__(self, other):
        return self.f < other.f # Priority queue comparison
    def heuristic(a, b):
        return abs(a[0] - b[0]) + abs(a[1] - b[1]) # Manhattan Distance
    def a_star(grid, start, goal):
        rows, cols = len(grid), len(grid[0])
        open_list = []
        heapq.heappush(open_list, Node(start, None, 0,
            heuristic(start, goal)))
        closed_set = set()
        while open_list:
            current_node = heapq.heappop(open_list) # Get node with
            lowest f-value
            if current_node.position == goal:
                path = []
                while current_node:
                    path.append(current_node.position)
                    current_node = current_node.parent
                return path[::-1] # Return reversed path

            closed_set.add(current_node.position)
            for dr, dc in [(-1, 0), (1, 0), (0, -1), (0, 1)]: # Possible moves
                new_pos = (current_node.position[0] + dr,
                    current_node.position[1] + dc)
                if (0 <= new_pos[0] < rows and 0
                    <= new_pos[1] < cols and
                    grid[new_pos[0]][new_pos[1]] == 0 and new_pos not in closed_set):
                    new_node = Node(new_pos, current_node, current_node.g + 1,

```

```
        heuristic(new_pos, goal))
        heapq.heappush(open_list, new_node)
    return None # No path found
# Example grid: 0 = free space, 1 = obstacle
warehouse_grid = [
    [0, 0, 0, 0, 1],
    [1, 1, 0, 1, 0],
    [0, 0, 0, 0, 0],
    [0, 1, 1, 1, 0],
    [0, 0, 0, 0, 0]
]
start_position = (0, 0)
goal_position = (4, 4)
path = a_star(warehouse_grid, start_position, goal_position)
print("Optimal Path:", path)
```

Output:

```
Optimal Path: [(0, 0), (0, 1), (0, 2), (1, 2), (2, 2), (2, 3), (2, 4), (3, 4), (4, 4)]
```
